

Bond-related article counts in three-month event-time windows

Average three-month total; monthly city counts winsorized at 9 articles

Notes: The event window contains months 0 through 2. Election observations exactly match the 699-proposition media-election regression universe. Each proposition is separate, including propositions held together. The event-time panel is unbalanced; an event enters a bin whenever all three months are observed. The RavenPack panel ends in December 2020, so the 64 regression elections held in 2021 contribute only to observable pre-event bins. Bin-specific N ranges from 620 to 682 elections and 387 to 402 issuances.
